# 7: Optimal FIR filters

## Optimal Filter Design

- 1 FIR Filter Design by “windowing” is straight-forward.

## Optimal Filter Design

- 1 FIR Filter Design by “windowing” is straight-forward.
- 2 However, it has limitations. “Poor Approximation” at discontinuities.

## Optimal Filter Design

- 1 FIR Filter Design by “windowing” is straight-forward.
- 2 However, it has limitations. “Poor Approximation” at discontinuities.
- 3 For a given filter order “ $M$ ” can we design better?

# Optimal Filter Design

- 1 FIR Filter Design by “windowing” is straight-forward.
- 2 However, it has limitations. “Poor Approximation” at discontinuities.
- 3 For a given filter order “ $M$ ” can we design better?
- 4 This question is meaningless unless we introduce an approximation criterion!  
Why? From the basic theory of Fourier series, we have seen that the rectangular window gives the best least-squares approximation to a desired frequency response for a given value of  $M$ , because,

$$h[n] = \begin{cases} h_d[n] & m \in [0, M] \\ 0 & m \notin [0, M] \end{cases} \quad \text{minimizes} \quad \epsilon^2 = \int_{-\pi}^{\pi} |H_d(e^{j\omega}) - H(e^{j\omega})|^2 d\omega.$$

Problems with this strategy:

# Optimal Filter Design

- 1 FIR Filter Design by “windowing” is straight-forward.
- 2 However, it has limitations. “Poor Approximation” at discontinuities.
- 3 For a given filter order “ $M$ ” can we design better?
- 4 This question is meaningless unless we introduce an approximation criterion!  
Why? From the basic theory of Fourier series, we have seen that the rectangular window gives the best least-squares approximation to a desired frequency response for a given value of  $M$ , because,

$$h[n] = \begin{cases} h_d[n] & m \in [0, M] \\ 0 & m \notin [0, M] \end{cases} \quad \text{minimizes} \quad \varepsilon^2 = \int_{-\pi}^{\pi} |H_d(e^{j\omega}) - H(e^{j\omega})|^2 d\omega.$$

Problems with this strategy:

- 1 Due to the approximation criterion  $\arg \min_{h[n]} \varepsilon^2$ , the resulting design leads to problems at discontinuities.

# Optimal Filter Design

- ❶ FIR Filter Design by “windowing” is straight-forward.
- ❷ However, it has limitations. “Poor Approximation” at discontinuities.
- ❸ For a given filter order “ $M$ ” can we design better?
- ❹ This question is meaningless unless we introduce an approximation criterion!  
Why? From the basic theory of Fourier series, we have seen that the rectangular window gives the best least-squares approximation to a desired frequency response for a given value of  $M$ , because,

$$h[n] = \begin{cases} h_d[n] & m \in [0, M] \\ 0 & m \notin [0, M] \end{cases} \quad \text{minimizes} \quad \varepsilon^2 = \int_{-\pi}^{\pi} |H_d(e^{j\omega}) - H(e^{j\omega})|^2 d\omega.$$

Problems with this strategy:

- ❶ Due to the approximation criterion  $\arg \min_{h[n]} \varepsilon^2$ , the resulting design leads to problems at discontinuities.
- ❷ No way to “control” errors in the different bands, namely, *pass band*, *transition band* and the *stop band*.

# Optimal Filter Design

- ❶ FIR Filter Design by “windowing” is straight-forward.
- ❷ However, it has limitations. “Poor Approximation” at discontinuities.
- ❸ For a given filter order “ $M$ ” can we design better?
- ❹ This question is meaningless unless we introduce an approximation criterion!  
Why? From the basic theory of Fourier series, we have seen that the rectangular window gives the best least-squares approximation to a desired frequency response for a given value of  $M$ , because,

$$h[n] = \begin{cases} h_d[n] & m \in [0, M] \\ 0 & m \notin [0, M] \end{cases} \quad \text{minimizes} \quad \epsilon^2 = \int_{-\pi}^{\pi} |H_d(e^{j\omega}) - H(e^{j\omega})|^2 d\omega.$$

Problems with this strategy:

- ❶ Due to the approximation criterion  $\arg \min_{h[n]} \epsilon^2$ , the resulting design leads to problems at discontinuities.
- ❷ No way to “control” errors in the different bands, namely, *pass band*, *transition band* and the *stop band*.
- ❸ Our goal here is to study algorithmic procedures that overcome the above disadvantages.

- In our design, we will consider even-symmetric, causal filters.  
These boil down to polynomials of the form,

$$H(e^{j\omega}) = h[0] + 2 \sum_{m=1}^{M/2} h[m] \cos(m\omega).$$

To make it causal, multiply it with  $\exp(-j\omega M/2)$ . *shift by  $M/2$*

- The goal is to satisfy the design constraints based on  $M, \delta, \delta_s, \omega_p, \omega_s$ .

- Several algorithms have been proposed since the 70s. Namely, [Herrmann \(1970\)](#) and [Hofstetter, Oppenheim and Siegel \(1971\)](#) ( $M, \delta, \delta_s$  fixed but  $\omega_p, \omega_s$  are variable).
- [Parks and McClellan \(1972 onward\)](#) — **Minimax Criterion**.  
Developed the most flexible design:  $M, \delta, \delta_s, \omega_p, \omega_s$  are all variable.

Overall idea!

- Write higher order cosine frequencies in terms of "Chebyshev polynomial" or  $\cos(m\omega) = T_m(\cos \omega)$ .

Example:  $\cos(2\omega) = 2\cos^2(\omega) - 1 \Leftrightarrow T_2(x) = 2x^2 - 1$ .

Can be obtained recursively.

$$\underbrace{T_0(x) = 1 \quad T_1(x) = x}_{\text{Initialize}} \longleftrightarrow T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$$

Overall idea!

- Write higher order cosine frequencies in terms of "Chebyshev polynomial" or  $\cos(m\omega) = T_m(\cos \omega)$ .

Example:  $\cos(2\omega) = 2\cos^2(\omega) - 1 \Leftrightarrow T_2(x) = 2x^2 - 1$ .

Can be obtained recursively.

$$\underbrace{T_0(x) = 1 \quad T_1(x) = x}_{\text{Initialize}} \longleftrightarrow T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$$

- This transformation allows us to write:

$$H(e^{j\omega}) = h[0] + 2 \sum_{m=1}^{M/2} h[m] \cos(m\omega) \leftrightarrow \sum_{m=0}^{M/2} h_m (\underbrace{\cos(\omega)}_{x})^m \leftrightarrow \underbrace{\sum_{m=0}^{M/2} h_m x^m}_{\text{Polynomial}}$$

$h[m] \neq h_m$

or, in explicit polynomial form,

$$H(e^{j\omega}) = P(x)|_{x=\cos \omega}.$$

Overall idea!

- 1 Write higher order cosine frequencies in terms of "Chebyshev polynomial" or  $\cos(m\omega) = T_m(\cos \omega)$ .

Example:  $\cos(2\omega) = 2\cos^2(\omega) - 1 \Leftrightarrow T_2(x) = 2x^2 - 1$ .

Can be obtained recursively.

$$\underbrace{T_0(x) = 1 \quad T_1(x) = x}_{\text{Initialize}} \longleftrightarrow T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$$

- 2 This transformation allows us to write:

$$H(e^{j\omega}) = h[0] + 2 \sum_{m=1}^{M/2} h[m] \cos(m\omega) \leftrightarrow \sum_{m=0}^{M/2} h_m (\cos(\omega))^m \leftrightarrow \underbrace{\sum_{m=0}^{M/2} h_m x^m}_{\text{Polynomial}}$$

or, in explicit polynomial form,

$$H(e^{j\omega}) = P(x)|_{x=\cos \omega}.$$

- 3 Then, the problem boils down to,

$$E(\omega) = \arg \min_{h[n]} \textcolor{red}{W}(\omega) (H_d(e^{j\omega}) - H(e^{j\omega})) \equiv \min_{h[m], 0 \leq m \leq M/2} \left( \max_{\omega} |E(\omega)| \right).$$

This is a well studied problem in approximation theory (alteration theorem!).

Overall idea!

- 1 Write higher order cosine frequencies in terms of "Chebyshev polynomial" or  $\cos(m\omega) = T_m(\cos \omega)$ .

Example:  $\cos(2\omega) = 2\cos^2(\omega) - 1 \Leftrightarrow T_2(x) = 2x^2 - 1$ .

Can be obtained recursively.

$$\underbrace{T_0(x) = 1 \quad T_1(x) = x}_{\text{Initialize}} \longleftrightarrow T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$$

- 2 This transformation allows us to write:

$$H(e^{j\omega}) = h[0] + 2 \sum_{m=1}^{M/2} h[m] \cos(m\omega) \leftrightarrow \sum_{m=0}^{M/2} h_m (\cos(\omega))^m \leftrightarrow \underbrace{\sum_{m=0}^{M/2} h_m x^m}_{\text{Polynomial}}$$

or, in explicit polynomial form,

$$H(e^{j\omega}) = P(x)|_{x=\cos \omega}.$$

- 3 Then, the problem boils down to,

$$E(\omega) = \arg \min_{h[n]} \textcolor{red}{W}(\omega) (H_d(e^{j\omega}) - H(e^{j\omega})) \equiv \min_{h[m], 0 \leq m \leq M/2} \left( \max_{\omega} |E(\omega)| \right).$$

This is a well studied problem in approximation theory (alteration theorem!).

- 4 Turns out that we do not have to know the relationship between polynomial coefficients  $h_m$  and the filter impulse response  $h[m]$ .

Basic statement of the alteration theorem.

- Suppose that  $X_p$  is a closed subset consisting of the disjoint union of closed subsets of the real axis  $x$ .
- Let  $P(x)$  be a polynomial of degree  $r$ , namely,

$$P(x) = \sum_{m=0}^r p_m x^m.$$

- Let us define the weighted error on each interval/subset  $X_p$  as,

$$E_p(x) = W_p(x) (D_p(x) - P(x))$$

where  $D_p$  is the desired function to be approximated.

Basic statement of the alteration theorem.

- Suppose that  $X_p$  is a closed subset consisting of the disjoint union of closed subsets of the real axis  $x$ .
- Let  $P(x)$  be a polynomial of degree  $r$ , namely,

$$P(x) = \sum_{m=0}^r p_m x^m.$$

- Let us define the weighted error on each interval/subset  $X_p$  as,

$$E_p(x) = W_p(x) (D_p(x) - P(x))$$

where  $D_p$  is the desired function to be approximated.

The sufficient and necessary condition that  $P(x)$  is a unique minimizer of error  $\|E\| = \max_{x \in X_p} |E(x)|$  is that there are **at least  $r + 2$**  sign alterations or,

$$x_k \in X_p, \quad x_1 < x_2 < \cdots < x_{r+2} \text{ such that } E_p(x_k) = -E_p(x_{k+1}) = \pm \|E\| = \max_{x \in X_p} |E(x)|$$

Example. Consider  $r = 5$ .  $X_1 = [-1, -0.1]$  and  $X_2 = [0.1, 1]$ . Let  $D_p$  be defined by,

$$D_p(x) \begin{cases} 1 & x \in X_1 \\ 0 & x \in X_2. \end{cases}$$

From "Alteration Theorem" *at least*  $r + 2 = 7$  sign changes!  $P_1(x)$  and  $P_2(x)$  do not satisfy this condition.  $P_3(x)$  is the correct 5th order polynomial.

$$\overline{H}(\omega) = H(e^{j\omega}) = h[0] + 2 \sum_{n=1}^{\frac{M}{2}} h[n] \cos n\omega$$

But  $\cos n\omega = T_n(\cos \omega)$ : Chebyshev polynomial of 1st kind

$$\cos 2\omega = 2 \cos^2 \omega - 1 = T_2(\cos \omega)$$

$$T_2(x) = 2x^2 - 1$$

$$\cos 3\omega = 4 \cos^3 \omega - 3 \cos \omega = T_3(\cos \omega)$$

$$T_3(x) = 4x^3 - 3x$$

Recurrence Relation:

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x) \text{ with } T_0(x) = 1, T_1(x) = x$$

**Proof:**  $\cos(n\omega + \omega) + \cos(n\omega - \omega) = 2 \cos \omega \cos n\omega$

# Chebyshev Polynomials

## 7: Optimal FIR filters

- Optimal Filters
  - Alternation Theorem
  - Chebyshev Polynomials
  - Maximal Error Locations
  - Remez Exchange
- Algorithm
- Determine Polynomial
  - Example Design
  - FIR Pros and Cons
  - Summary
  - MATLAB routines

$$\overline{H}(\omega) = H(e^{j\omega}) = h[0] + 2 \sum_{n=1}^{\frac{M}{2}} h[n] \cos n\omega$$

But  $\cos n\omega = T_n(\cos \omega)$ : Chebyshev polynomial of 1st kind

$$\cos 2\omega = 2 \cos^2 \omega - 1 = T_2(\cos \omega)$$

$$T_2(x) = 2x^2 - 1$$

$$\cos 3\omega = 4 \cos^3 \omega - 3 \cos \omega = T_3(\cos \omega)$$

$$T_3(x) = 4x^3 - 3x$$

Recurrence Relation:

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x) \text{ with } T_0(x) = 1, T_1(x) = x$$

**Proof:**  $\cos(n\omega + \omega) + \cos(n\omega - \omega) = 2 \cos \omega \cos n\omega$

So  $\overline{H}(\omega)$  is an  $\frac{M}{2}$  order polynomial in  $\cos \omega$ : alternation theorem applies.

# Chebyshev Polynomials

## 7: Optimal FIR filters

- Optimal Filters
- Alternation Theorem
- Chebyshev Polynomials
- Maximal Error Locations
- Remez Exchange
- Algorithm
- Determine Polynomial
- Example Design
- FIR Pros and Cons
- Summary
- MATLAB routines

$$\overline{H}(\omega) = H(e^{j\omega}) = h[0] + 2 \sum_{n=1}^{\frac{M}{2}} h[n] \cos n\omega$$

But  $\cos n\omega = T_n(\cos \omega)$ : Chebyshev polynomial of 1st kind

$$\cos 2\omega = 2 \cos^2 \omega - 1 = T_2(\cos \omega)$$

$$T_2(x) = 2x^2 - 1$$

$$\cos 3\omega = 4 \cos^3 \omega - 3 \cos \omega = T_3(\cos \omega)$$

$$T_3(x) = 4x^3 - 3x$$

Recurrence Relation:

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x) \text{ with } T_0(x) = 1, T_1(x) = x$$

**Proof:**  $\cos(n\omega + \omega) + \cos(n\omega - \omega) = 2 \cos \omega \cos n\omega$

So  $\overline{H}(\omega)$  is an  $\frac{M}{2}$  order polynomial in  $\cos \omega$ : alternation theorem applies.

Example: Symmetric lowpass filter of order  $M = 4$

$$H(z) = 0.1766z^2 + 0.4015z + 0.2124 + 0.4015z^{-1} + 0.1766z^{-2}$$

3. **Find the local maxima** of the error function by evaluating  $e(\omega) = s(\omega) (\overline{H}(\omega) - d(\omega))$  on a dense set of  $\omega$ .
4. **Update the maximal error frequencies** to be an alternating subset of the local maxima + band edges +  $\{0 \text{ and/or } \pi\}$ .  
If maximum error is  $> \epsilon$ , go back to step 2. (typically 15 iterations)
5. **Evaluate**  $\overline{H}(\omega)$  on  $M + 1$  evenly spaced  $\omega$  and do an **IDFT** to get  $h[n]$ .

## Remex Step 2: Determine Polynomial

### Method 1:

Solve  $\frac{M}{2} + 2$  equations in  $\frac{M}{2} + 2$  unknowns for  $h[n] + \epsilon$ .

In step 3, evaluate  $\overline{H}(\omega) = h[0] + 2 \sum_{n=1}^{\frac{M}{2}} h[n] \cos n\omega_i$

## Remex Step 2: Determine Polynomial

### 7: Optimal FIR filters

- Optimal Filters
- Alternation Theorem
- Chebyshev Polynomials
- Maximal Error Locations
- Remez Exchange

#### Algorithm

- Determine Polynomial
- Example Design
- FIR Pros and Cons
- Summary
- MATLAB routines

For each extremal frequency,  $\omega_i$  for  $1 \leq i \leq \frac{M}{2} + 2$

$$d(\omega_i) = \overline{H}(\omega_i) + \frac{(-1)^i \epsilon}{s(\omega_i)} = h[0] + 2 \sum_{n=1}^{\frac{M}{2}} h[n] \cos n\omega_i + \frac{(-1)^i \epsilon}{s(\omega_i)}$$

**Method 1:** (Computation time  $\propto M^3$ )

Solve  $\frac{M}{2} + 2$  equations in  $\frac{M}{2} + 2$  unknowns for  $h[n] + \epsilon$ .

In step 3, evaluate  $\overline{H}(\omega) = h[0] + 2 \sum_{n=1}^{\frac{M}{2}} h[n] \cos n\omega_i$

## Lagrange Interpolation.

$$\underbrace{\left[ \begin{array}{cc} x_0 & y_0 \\ \vdots & \vdots \\ x_K & y_K \end{array} \right]}_{\text{Set of Points in } \mathbb{R}^2} \xrightarrow{\text{Lagrange Interpolation}} L_K(x) = \sum_{k=0}^K y_k \ell_k(x)$$

where,

$$\ell_k(x) = \prod_{m \in [0, K], m \neq k} \frac{x - x_m}{x_k - x_m}.$$

## Lagrange Interpolation.

$$\underbrace{\left[ \begin{array}{cc} x_0 & y_0 \\ \vdots & \vdots \\ x_K & y_K \end{array} \right]}_{\text{Set of Points in } \mathbb{R}^2} \xrightarrow{\text{Lagrange Interpolation}} L_K(x) = \sum_{k=0}^K y_k \ell_k(x)$$

where,

$$\ell_k(x) = \prod_{m \in [0, K], m \neq k} \frac{x - x_m}{x_k - x_m}.$$

For the filter design problem, we have,

$$\overline{H}(e^{j\omega}) = \sum_{m=0}^{M/2} h_m (\cos(\omega))^m \equiv \sum_{m=0}^{M/2} h_m x^m \quad (\text{Polynomial}).$$

## Lagrange Interpolation.

$$\underbrace{\left[ \begin{array}{cc} x_0 & y_0 \\ \vdots & \vdots \\ x_K & y_K \end{array} \right]}_{\text{Set of Points in } \mathbb{R}^2} \xrightarrow{\text{Lagrange Interpolation}} L_K(x) = \sum_{k=0}^K y_k \ell_k(x)$$

where,

$$\ell_k(x) = \prod_{m \in [0, K], m \neq k} \frac{x - x_m}{x_k - x_m}.$$

For the filter design problem, we have,

$$\overline{H}(e^{j\omega}) = \sum_{m=0}^{M/2} h_m (\cos(\omega))^m \equiv \sum_{m=0}^{M/2} h_m x^m \quad (\text{Polynomial}).$$

Hence, we can write,

$$\left[ \begin{array}{cc} \omega_0 & \overline{H}(e^{j\omega_0}) \\ \vdots & \vdots \\ \omega_K & \overline{H}(e^{j\omega_K}) \end{array} \right] \xrightarrow{\text{Lagrange Interpolation}} L_K(\omega) = \sum_{k=0}^K \overline{H}(e^{j\omega_k}) \ell_k(\omega)$$

$$\ell_k(\omega) = \prod_{m \in [0, K], m \neq k} \frac{\cos(\omega) - \cos(\omega_m)}{\cos(\omega_k) - \cos(\omega_m)}$$

## Remex Step 2: Determine Polynomial

### 7: Optimal FIR filters

- Optimal Filters
- Alternation Theorem
- Chebyshev Polynomials
- Maximal Error Locations
- Remez Exchange

#### Algorithm

- Determine Polynomial
- Example Design

### Filter Specifications:

Bandpass  $\omega = [0.5, 1]$ , Transition widths:  $\Delta\omega = 0.2$

Stopband Attenuation:  $-25$  dB and  $-15$  dB

Passband Ripple:  $\pm 0.3$  dB

Determine **gain tolerances** for each band:

$$-25 \text{ dB} = 0.056, -0.3 \text{ dB} = 1 - 0.034, -15 \text{ dB} = 0.178$$

Predicted order:  $M = 36$

$\frac{M}{2} + 2$  extremal frequencies are distributed between the bands

Filter meets specs ☺; clearer on a decibel scale

Most zeros are on the unit circle + three **reciprocal pairs**

# Example Design

## Filter Specifications:

Bandpass  $\omega = [0.5, 1]$ , Transition widths:  $\Delta\omega = 0.2$

Stopband Attenuation:  $-25$  dB and  $-15$  dB

Passband Ripple:  $\pm 0.3$  dB

Determine **gain tolerances** for each band:

$$-25 \text{ dB} = 0.056, -0.3 \text{ dB} = 1 - 0.034, -15 \text{ dB} = 0.178$$

Predicted order:  $M = 36$

$\frac{M}{2} + 2$  extremal frequencies are distributed between the bands

Filter meets specs ☺; clearer on a decibel scale

Most zeros are on the unit circle + three **reciprocal pairs**

Reciprocal pairs give a linear phase shift

# FIR Pros and Cons

## 7: Optimal FIR filters

- Optimal Filters
- Alternation Theorem
- Chebyshev Polynomials
- Maximal Error Locations
- Remez Exchange Algorithm
- Determine Polynomial
- Example Design
- **FIR Pros and Cons**
- Summary
- MATLAB routines

- Can have **linear phase**
  - no envelope distortion, all frequencies have the same delay 😊
  - symmetric or antisymmetric:  $h[n] = h[-n]\forall n$  or  $-h[-n]\forall n$
  - antisymmetric filters have  $H(e^{j0}) = H(e^{j\pi}) = 0$
  - symmetry means you only need  $\frac{M}{2} + 1$  multiplications to implement the filter.

# FIR Pros and Cons

## 7: Optimal FIR filters

- Optimal Filters
- Alternation Theorem
- Chebyshev Polynomials
- Maximal Error Locations
- Remez Exchange Algorithm
- Determine Polynomial
- Example Design
- **FIR Pros and Cons**
- Summary
- MATLAB routines

- Can have **linear phase**
  - no envelope distortion, all frequencies have the same delay 😊
  - symmetric or antisymmetric:  $h[n] = h[-n]\forall n$  or  $-h[-n]\forall n$
  - antisymmetric filters have  $H(e^{j0}) = H(e^{j\pi}) = 0$
  - symmetry means you only need  $\frac{M}{2} + 1$  multiplications to implement the filter.
- Always **stable** 😊

# FIR Pros and Cons

## 7: Optimal FIR filters

- Optimal Filters
- Alternation Theorem
- Chebyshev Polynomials
- Maximal Error Locations
- Remez Exchange Algorithm
- Determine Polynomial
- Example Design
- **FIR Pros and Cons**
